

# AGILE PRESENTATION

Sydney Martin

# The Agile Roles

- Every single member of an Agile Team is incredibly important. One team cannot work to its fullest potential if they are missing even one member.
  - **Product Owner** – The one who represents the business and the customers, prioritizing backlog, providing priority decisions but deferring to the team's expertise. They ensure that the team builds the right product with the specifications laid out by the client and without a Product Owner the team doesn't have the correct insight and direction needed to proceed.
  - **Scrum Master** – Scrum Masters play an important role by outlining sprints and daily meetings, ensuring that the team stays on top of their tasks. They maintain communication and keeps the team aligned, whilst also removing obstacles that might be in the way for the team to continue at their pace.
  - **Developers** – During Sprints the developers are the ones creating the product and working their ideas and the feedback from user stories and test cases into what will become the final product. Truly without developers, there would be no product in the end. Open communication between testers is essential for ensuring that all specifications and requirements are met during the development phase(s).
  - **Testers** – Another integral part of the team, as they are the ones assuring the quality and performance of the product. They focus and ensure the product works as its designed and intended; preventing bugs in the code and no drops in quality at any stage. Without people in this role, there would be no one to ensure the products quality remains intact for the final delivery of the product.

- For the Agile approach, there are six key phases that define the Software Development Lifecycle.

### 1. **Defining the Requirements**

1. Based on the client's needs and user stories provided, the Product Owner was able to accumulate and produce a backlog with clear, immediate priorities and requirements for the team. From there the team was able to decipher what their own priorities were in the development cycle and could begin working towards their goals outlined during daily meetings through each sprint. With any adjustments, changes or concerns that were directed to us by the client we were easily able to reconfigure and pivot, ensuring that their final product was up to our standards and their specifications.

### 2. **Design**

1. Small and manageable pieces were designed based on the current sprint. Utilizing the information from the user stories and the specifications of the client, the team was able to move forward in small bursts, working on small and specific portions of the product to be completed weekly. During this time, we had daily meetings in the morning to ensure that each team member was on top of their tasks and that there were no disruptions causing any hinderances or obstacles in their way.

### 3. **Development & Coding**

1. Goals were set in place and the team worked individually and collaboratively on each of their assigned parts of the project. With the daily meetings we were able to see what everyone accomplished daily, while also opening the floor to any concerns that arose during these short bursts of development.

### 4. **Testing**

1. Testing coincided with development due to the Agile approach, which allowed us to work a little more efficiently. When we were approached to pivot to some niche vacation packages for wellness and detox vacations, the developers and testers worked closely with one another to ensure that each changed portion of the product was still meeting the earlier set requirements, and that there were no new bugs that arose when the coding was changed from its earlier state.

### 5. **Release**

1. Upon completion of the product, the Scum Master and Product Owner approached the SNHU Travel Team with the final version. With their specifications met and the client happy with the results, we were quickly able to deploy and release the new website to cater to new customers for SNHU Travel. The website ultimately featured new, niche vacation packages that focused on wellness and detox packages, complete with a gallery of images per destination, locale information and package pricing easily accessible for customers visiting the site.

### 6. **Maintenance**

1. A final sprint review was conducted with the Product Owner to ensure and outline any maintenance that might be required in the future; bugs in the code or security flaws, to ensure that the product being displayed is always maintaining the quality we promised with the vision the SNHU Travel Team had in mind.

# The Agile Phases

# Waterfall Model

- Everyone can expect bugs, unforeseen circumstances and last-minute changes to occur during the development phased of a product. Things naturally change along the way! Ensuring that those changes are met and that the vision of the client remains just as they expect is imperative, therefore the approach must be significant.
- The Waterfall Model is a more linear, rigid approach than Agile. Had we had gone with the Waterfall Model instead of the Agile we would have been met with many more speedbumps and disruptions along the way.
- Midway during the development phase we were met with a pivot in ideas to different travel packages. Had we been working from the Waterfall model, the changes we would have made to the software would have taken much longer, which would have resulted in not meeting sprint goals the team had in place, or even worse, exceeding the deadline set for us.
- Because of the placement of the pivot in development, if we had been on the Waterfall Model we would have had to develop what was already in process and test it before we could even work on implementing the changes the client approached us with. The Waterfall Model does offer its own advantages but unfortunately would have proven to be more of a hinderance considering the time and resources that had already been put into the product we were creating for the SNHU Travel Team.

# Waterfall or Agile

- No two projects are ever the same. Waterfall and Agile are both very viable approaches for any project. Agile offers a more flexible approach whereas Waterfall is more straightforward and offers a linear and more approachable outline.
  - Waterfall offers a full scope of the project at the beginning, with clear goals from beginning to end outlined and defined, locked in.
  - Agile provides a more flexible approach, with requirements adjusting throughout the project's development based on weekly sprints outlined by the Scrum Master and with feedback from the development team.
- Each approach has its own risks as well as its own rewards. The Waterfall approach cannot be tested incrementally like the Agile approach can, which means any bugs or flaws that appear during the testing phase aren't realized until towards the end of development. With the Agile approach, testing and development are done together, which allows for flaws to be discovered much quicker and fixed in a timely manner.
- Self-organization and collaboration are vital when it comes to the Agile method, which works seamlessly in some groups rather than others, which is another factor to consider when deciding which method works for a project. The Agile approach offers an open, team building collaboration where each team member is aware of where their peers are at in each stage of development. Because of this, they are also encouraged to work with one another when there are lulls or hiccups in development, ensuring that everyone can move on together to the next step, as outline during the sprint planning.
